

Good stability, but weak layers are concerning.

Activity

Snowmobiling

The snowpack turned out to be more stable than I had expected. 90cm at elevation with descent cohesion. 10cm of new snow. Compression test resulted in a CTN. Extended column test resulted in ECTX. I am still wary of some wind loaded drifts that could crack or [collapse](#) but didn't find any. There is a weak faceted layer about 20cm down that could become a problem with a new load of snow.
